Handwashing was proved to be effective in preventing infection. Dr. Ignatz Semmelweis, in 1847, demonstrated that “childbed fever” was contagious and that its incidence could be reduced from 13% to 2% or less by enforcing appropriate handwashing behavior by medical caregivers.

The London Cholera epidemic of 1854 gave birth to modern epidemiology. The outbreak, largely confined to Soho, was traced to a contaminated well pump on Broad Street by Dr. John Snow, who later mapped the results. The earliest precursor of today’s Weekly Morbidity & Mortality Reports, the Weekly Returns of Births and Deaths, endorsed Snow’s conclusions and germ theory becomes the foundation for modern public health.

“Typhoid Mary” demonstrated the risk of ill food workers by causing two strings of Salmonella infections in New York between 1906 and 1922. This also raised awareness of the asymptomatic carrier. At least 47 infections and three deaths were traced to Mary Mallon, who in the second half of her career cooked for, and infected, a maternity hospital. However, inspectors focused on the cleanliness of floors, walls and ceilings.

New bacterial risks have been recognized since World War II; at the same time our culture has been restaurantized. The eating out trend exploded — in 1970, Americans spent 34% of their food dollar eating out; by 1995 this had grown to 46%. In 1958, six major foodborne pathogens were recognized; by 1999, the CDC acknowledged 28 major foodborne pathogens. At least 47 infections and three deaths were traced to Mary Mallon, who in the second half of her career cooked for, and infected, a maternity hospital. However, inspectors focused on the cleanliness of floors, walls and ceilings.

Jack-in-the-Box outbreak (1992) creates a new awareness of risk and the importance of temperature control. More than 500 people developed E. coli infections and four children died. The foodservice industry recognizes the need for food safety training. Positive identification of outbreak organisms and their source – specific foodservice establishments and individual ill workers – is now possible.

Creation of PulseNet (1996) resulted in more people looking for outbreaks. CDC scientists perform DNA fingerprinting to isolate the source of the outbreak. Increased knowledge again does little to change handwashing behavior. Positive identification of outbreak organisms and their source – specific foodservice establishments and individual ill workers – is now possible.

Mariel Clark and the legal principle of strict liability defines risk in terms of dollars ($15.6 million in the Jack-in-the-Box settlement alone) and brand damage. Operators awaken. Industry responds with advances in temperature control and increased insurance. Lost opportunity due to brand damage is estimated in hundreds of millions.

Viruses join the bacterial enemies: Hepatitis A virus and a newly identified viral pathogen, Norwalk virus, later renamed norovirus – which is tagged as the agent of 66% of the foodborne illness in the US. CDC’s Vessel Sanitation defines risk in terms of dollars ($15.6 million in the Jack-in-the-Box settlement alone) and brand damage. Operators awaken. Industry responds with advances in temperature control and increased insurance. Lost opportunity due to brand damage is estimated in hundreds of millions.

New research presents compelling data on preventing foodservice norovirus outbreaks through handwashing and hand sanitizing. July, 2007. Dr. C.L. Moe of Emory University and Lee Ann Jaykus Ph.D. at North Carolina State publish new research data, helping to understand the risk of norovirus. Will findings motivate foodservice management to raise hand hygiene as an operational priority?

Trivialization of handwashing is as old as civilization. “People died from a lot of things but not from poor handwashing…” History, however, gives us many examples of epidemics that were caused by diseases that can be facilitated by poor handwashing. Empires have been destroyed by infectious disease, killing many more than the wars around the world. For example:

- Ancient Athens was decimated by a plague during the Peloponnesian War in 430 BCE, described by Thucydides, the earliest historian (who survived the plague itself). Pericles, the orator and architect of the Parthenon, was a victim. Recent DNA examination of victims from a mass grave suggests they died of typhus – that is, Salmonella typhi.
- Earlier, the Assyrian siege of Jerusalem (circa 700 BCE) may have been dropped due to choler.
- George Washington suffered from “the bloody flux [diarrhea]” – possibly shigella - during his service on General Braddock’s march to Fort Duquesne (now Pittsburgh, PA) during the French and Indian War – the British (and Washington) lost.

Handwashing for Life Institute, 1991-2010

A 10-Point History Lesson of poor handwashing

Compelling lessons continue with little effect on handwashing compliance

Trivialization of handwashing is as old as civilization. “People died from a lot of things but not from poor handwashing…” History, however, gives us many examples of epidemics that were caused by diseases that can be facilitated by poor handwashing. Empires have been destroyed by infectious disease, killing many more than the wars around the world. For example:

- Ancient Athens was decimated by a plague during the Peloponnesian War in 430 BCE, described by Thucydides, the earliest historian (who survived the plague itself). Pericles, the orator and architect of the Parthenon, was a victim. Recent DNA examination of victims from a mass grave suggests they died of typhus – that is, Salmonella typhi.
- Earlier, the Assyrian siege of Jerusalem (circa 700 BCE) may have been dropped due to choler.
- George Washington suffered from “the bloody flux [diarrhea]” – possibly shigella - during his service on General Braddock’s march to Fort Duquesne (now Pittsburgh, PA) during the French and Indian War – the British (and Washington) lost.
